What is Impact Measurement?

What is Impact Measurement for start-ups?

It involves...

- Collecting data,
- Analysing outcomes, and
- Evaluating how a startup's products, services, or operations affect various stakeholders and the broader community.

Impact measurement is...

the process of quantifying & assessing the social environmental and economic effects or changes resulting from the activities of a start-up.

Why is Impact Measurement Important, and so what?

Why is Impact Measurement Important for climate start-ups?

Marketing & Sales

**Fundraising &
Investor traction**

**Supply Chain, Strategy
& Improvements**

Legal Compliance

Why is Impact Measurement Important for climate start-ups?

Marketing & Sales

- Competitive Advantage
- Transparency & Trust

Fundraising & Investor traction

- Showcase impacts and increase investor interest

Supply Chain, Strategy & Improvements

- Continuous Improvement
- Innovation & Adaptation

Legal Compliance

- Complying with sustainability regulation

So What?

Self-Assessment Comparative Approach

Conventional Product

Innovation

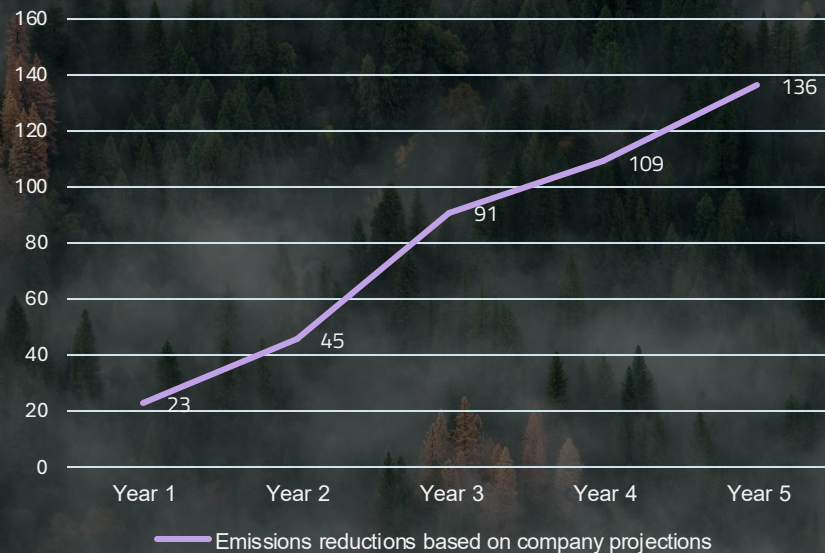

Extraction	→	Extraction	30%
Manufacturing		Manufacturing	20%
Transportation	→	Transportation	30%
Use		Use	10 %
After-Life		After-Life	10%

Emission Projections

based on the sales projections

Annual Planned Avoided GHG emissions
(t CO2 eq)

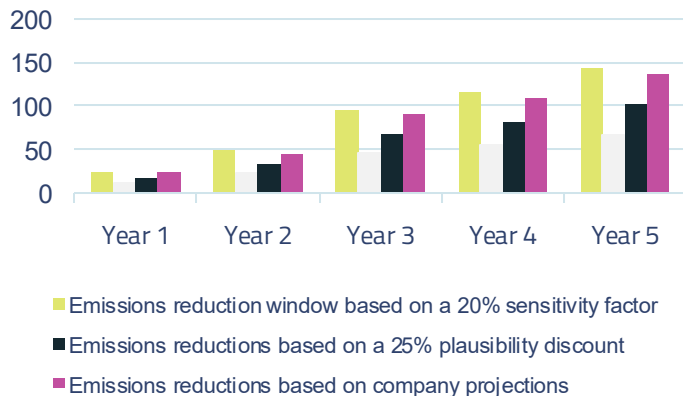

So What?

1. Highest emission
2. Sensitivity analysis
3. Plausibility discount

Sensitivity Analysis & Plausibility Discount

Avoided GHG emissions (t CO₂ eq) based on sensitivity factor and plausibility discount

Emission Projections

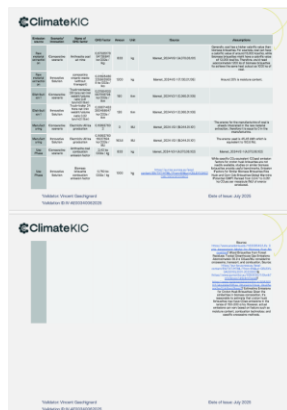

based on the sales projections

Annual Planned Avoided GHG emissions
(t CO₂ eq)

So What?

How can Environmental Impact be Measured?

Introduction: Environmental Impact Measurement

- There are many methodologies for measuring and/or projecting the environmental impact of a business.
- While different methods have different strengths and limitations, there is not a 'unicorn' or perfect methodology.
- Impact measurement and projection methodologies tend to include a unit of measure and many are governed by standards and frameworks.

What is a Unit of Measurement?

- A unit of measure for environmental impact is used to quantify the impact of a particular environmental factor.
- Using a single unit of measure allows us to easily compare or aggregate data.

Some common units of measure include:

Carbon Dioxide
equivalent (CO₂e)

A standard unit for
measuring greenhouse
gas emissions.

Kilowatt-hour
(kWh)

Used to measure
electricity consumption
or production

Cubic metres
(m³)

Used to measure the
volume of water
consumed to produce
goods/services

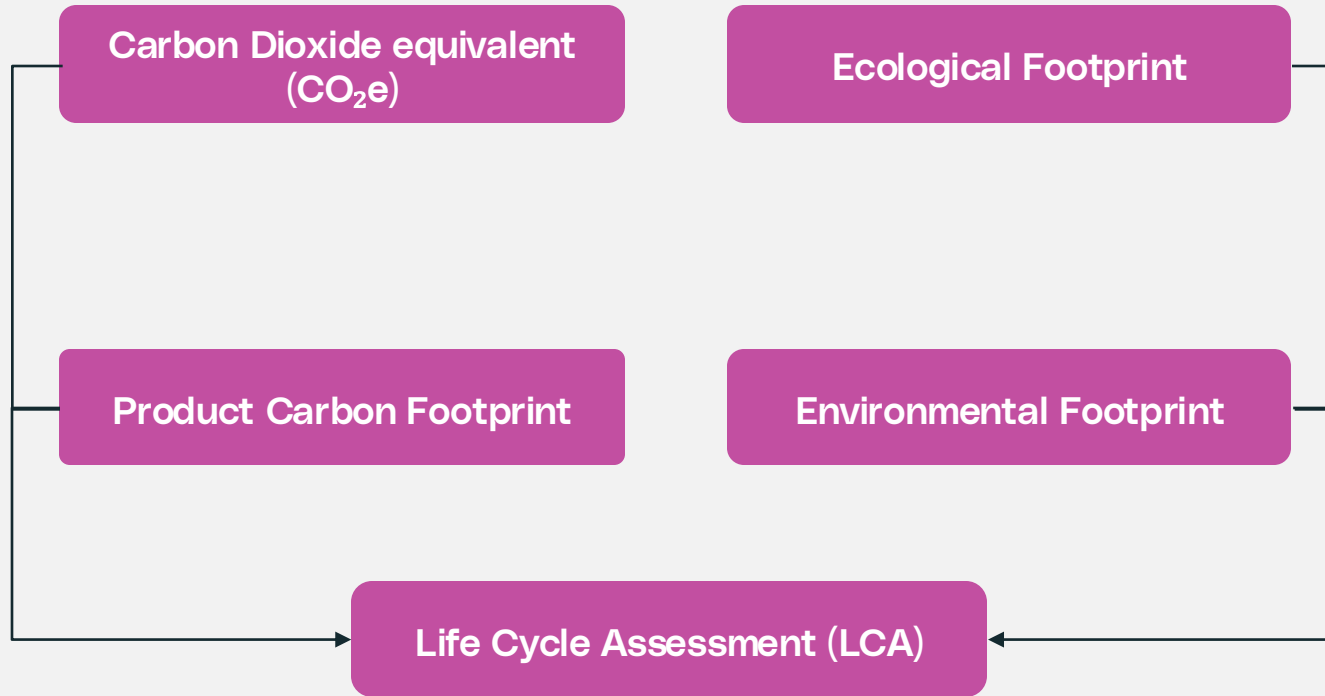

Hectares
(ha)

Used to quantify the
amount of land
required to support a
particular activity

How can Environmental Impact be Measured?

Environmental Impact Labels & Methods

EUDR	EU Deforestation Regulation
SCM	Supply Chain Management

Focus: Life Cycle Assessment

Where Do We Sit?

Unit of Analysis x Methods

From Lina Kindermann, 2025

The Product Life Cycle

- The Life Cycle Assessment (LCA) is a comprehensive methodology which takes into account the environmental impact of a product or service throughout its entire life cycle.
- The life cycle includes five stages, this is sometimes referred to as 'from cradle to grave'.

1. Raw Material Extraction
2. Manufacturing & Processing
3. Transportation
4. Usage
5. End of Life

Five Stages of the Product Life Cycle

RAW MATERIAL EXTRACTION

Obtaining the raw materials for your product or service. This can include activities like mining, logging, farming, or other processes involved in extracting materials required for manufacture.

MANUFACTURING & PROCESSING

Processing and transforming the extracted materials into the final product. This can include activities such as manufacturing, shaping, assembling and packaging.

TRANSPORTATION

Transporting the product from the manufacturing facility to distribution centres, retailers and ultimately to end-users. This can include various forms of transport, such as road, rail, air and sea.

USAGE

The period in which the consumer uses the product for its intended purpose. You can consider the energy consumption and other impacts associated with the product's use.

END OF LIFE

The disposal or end-of-life of the product. This stage includes waste handling whether it is through recycling, landfill, incineration or other means.

Tip: There may be transportation inputs at multiple stages of the product life cycle

Tip: In a comparative LCA, it is important to compare 'apples with apples', in other words products that have a similar functionality.

For example, you cannot compare a lighter with a single match, because a match is designed for single use. A better comparison would be between a lighter and a box of matches.

The Comparative LCA

A comparative life cycle assessment (LCA) involves comparing the environmental impacts of a product or service with another similar or comparable product or service.

For innovative or more sustainable products & services, this usually involves comparing your solution with the 'status quo', market leader, or industry average.

This allows you to compare and differentiate your product from competitors.

Life Cycle Assessment

Example: Limitations of the methodology

The Life Cycle Assessment is not a 'unicorn' solution for measuring climate impact and has faced some criticism in the following areas:

- **It is not systemic:** LCAs measure the environmental impact of products in isolation, without taking into consideration the implications and interactions of the wider system.
- **It doesn't take into account social implications:** LCAs do not measure the social or human implications of the product or service they measure.
- **Calculations are often based on averages or samples:** LCAs often rely on databases of 'industry average' data, leading to criticisms over the accuracy of the methodology.

A Deeper Dive

Tip: In a comparative LCA, it is important to compare 'apples with apples', in other words products that have a similar functionality.

Key question:

What is the function of your product/service and how do you measure that function?

Step 1: Story of Your Innovation

When beginning a Life Cycle Assessment, it is important to ask some basic questions which will help to guide you through the process.

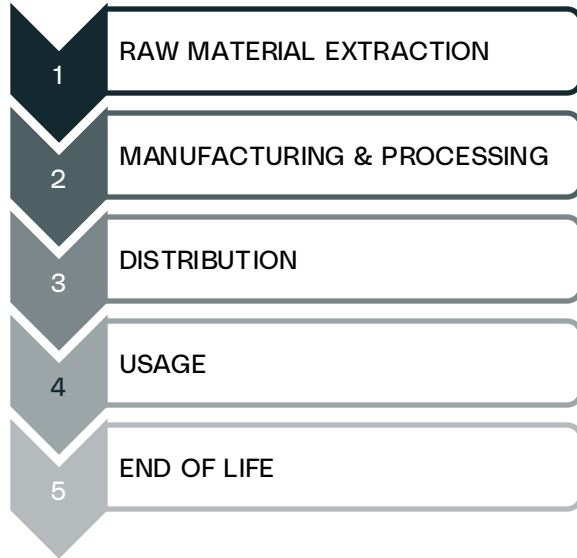

Describe the story of your innovation:

- What is the name of your solution?
- What kind of solution is it: a product, a service or both?
- Who is the customer or target group of your solution?

Define your comparative scenario:

- Identify the product or service that you want to replace in the market.

Step 2: Inventory Analysis

- The inventory analysis phase looks at all of the inputs and outputs involved in the life cycle of a product or service.
- You will describe of all the inputs and outputs.
- Depending on your product or service, this phase can be complex, and require a large amount of data.
- This phase is usually the most time consuming element of performing an LCA.

Key question:

**What data
do we
need?**

Key question:

**Where can I
find the data?**

Step 3: Scope of Analysis

Step 3: Scope of Analysis

Step 4: Quantities

	Your innovation Vs the comparative product	Comparative Scenario: Quantities per <i>Functional Unit</i>	Your Innovation: Quantities per <i>Functional Unit</i>
Raw Material Extraction	Raw materials	50 gr of Polyester pellets per t-shirt	500 gr of harvested cotton per t-shirt
Manufacturing	Manufacturing: Spinning	Polyester spun by melt spinning 125 MJ/kg --> 18.75 MJ/ t-shirt	Cotton spun by ring spinning 60MJ/kg --> 9MJ/ t-shirt
	Manufacturing: Dyeing	50gr of dyes --> 7.5 gr/t-shirt	30 gr of dyes --> 4.5 gr/t-shirt
Distribution 2	Transport of product to store	4: 8,800 tkm by cargo ship -> 1.32tkm	8,000km by plane --> 1.2 tkm/t-shirt

Step 4: Quantities & Emissions Factors

QUANTITIES PER INPUT

PHASES	COMPARATIVE SCENARIO: QUANTITIES PER FUNCTIONAL UNIT	YOUR INNOVATION: QUANTITIES PER FUNCTIONAL UNIT
Raw materials	50 gr of Polyester pellets per t-shirt	500 gr of harvested cotton per t-shirt
Manufacturing: Spinning	Polyester spun by melt spinning 125 MJ/kg --> 18.75 MJ/ t-shirt	Cotton spun by ring spinning 60MJ/kg --> 9MJ/ t-shirt
Manufacturing: Dyeing	50gr of dies --> 7.5 gr/t-Shirt	30 gr of dies --> 4.5 gr/t-shirt
Transport of product to store	4: 8,800 tkm by cargo ship --> 1.32tkm	8,000km by plane --> 1.2 tkm/t-shirt
